_____***______

Abstract - Now a days high rise buildings have become a common trend to accommodate the increasing population in urban areas. These high rise buildings are most commonly are made up of Reinforced concrete. The Reinforced concrete multi storey buildings are subjected to most dangerous earthquakes. The behavior of a building during an earthquake depends on several factors, stiffness, adequate lateral strength and ductility, simple and regular configurations. It was found that main reason for failure of RC building is irregularity in its plan dimension and its lateral force resisting system. At the time of any earthquake, failure of structure starts at points of weakness. This weakness arises due to discontinuity in mass, stiffness and geometry of structure. The structures having this discontinuity are termed as irregular structures. Irregularities are one of the major reasons of failures of structures during earthquakes. Among all the factors configuration of a building is an important feature which has huge influence on the damage during the earthquake shaking. The feature of the regularity and symmetry in the overall shape of the building both in plan and elevation enormously affects the response of the building under static and dynamic loading. But nowadays the need and demand of the modern era and growing population has made the architects or engineers forced towards planning of Buildings with Plan Irregularity. So if a structure has to perform well in earthquake means it should possess adequate strength, stiffness, ductility and simple configuration. Therefore these types of structures should be well designed under earthquake loading accounting the specified seismic design philosophies so that they can sustain moderate to strong earthquakes. The structures are carefully analyzed by using methods Equivalent static method of analysis and Dynamic method of analysis.

Key Words-ETABs, Response Spectrum Analysis, Irregular Building, Non-Parallel Lateral Force Resisting System, Time Period, Static Base Shear, Story Stiffness, Story Drift, Over Turning Moments, Design Forces.

1.INTRODUCTION

IS-1893-2016 (part 1) states that if a building possesses any of the following irregularity, the structure is to be considered as an irregular structure.

- 1) Torsional Irregularity
- 2) **Re-entrant Corners**
- 3) Floor Slabs having Excessive Cutouts or openings

- 4) Out of Plane offsets in vertical elements
- 5) Non-Parallel Lateral Force Resisting System
- 6) Stiffness Irregularity (Soft Storey)
- 7) Mass Irregularity
- 8) Vertical Geometric Irregularity
- 9) In-Plane Discontinuity in Vertical Elements **Resisting Lateral Force**
- 10) Strength Irregularity (Weak Storey)
- 11) Floating or Stub Column
- 12) Irregular Modes of Oscillation in Two Principal Plan Directions

Irregularities 1-5 are known as plan irregularities and when the lateral load resisting system is not oriented along mutually orthogonal horizontal directions, the structure shall be designed for the simultaneous effects due to full design earthquake load plus 30 percent of design earthquake along the other direction. Further if, effects due to vertical earthquake shaking are considered, 30 percent of vertical design earthquake load is also included while making load combinations of earthquake effects.

Regular building where the structure are formed by subsystems which are perpendicular among other and parallel with the global axes, the principal direction of the earthquake loads is parallel with that global axes. However, for the irregular building structure, mostly the direction of the principal axes could not be determined in advance. In this case, the principal direction of earthquake loads shall be calculated using trial & error for a number of possibilities. Hence, it is quite often the Structural Engineer has to perform quite a number of structural analyses of the building, applying static lateral loads in incremental direction angles, e.g. every 5 or 10 degrees to obtain the "maximum" results using a "trial and error" method.

In this paper an investigative study is made to find response of irregular structures having different orientation located in seismic zone V (Tower 1 and Tower 2). For this paper Tower 1 is oriented in Global X and Global Y direction, whereas Tower 2 is rotated 7^o in the anti-clockwise direction about the center. Analysis has been made by taking G+20 story building by static and dynamic methods using ETABS 2016 and IS code 1893-2016 (part1). Linear Equivalent Static analysis is performed for regular buildings up to 15m height in zone II, Dynamic Analysis should be performed for regular and irregular buildings in zone II, III, IV and V. Dynamic

Analysis is performed using a linear Response Spectrum Analysis. Behavior of building will be carefully studied in the light of IS-1893-2016 (part1) and comparing responses in the form of time period, static base shear, modal directional factors, modal participating mass ratios, stiffness, story displacement and design forces in an irregular structure having non-parallel lateral force resisting system with different orientation of the structure.

1.1 MODEL CONFIGURATION

Seismic Zone- V Response Reduction Factor, R- 5 Importance Factor, I- 1 Soil Type- Type II Height of the Building- 64 m Column Dimensions- (300X750) mm Beam Dimensions- (300X450) mm Slab Thickness- 200 mm

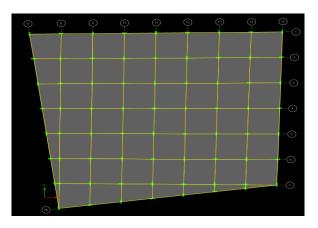

Figure 1.1(b) – Plan View of Tower 2

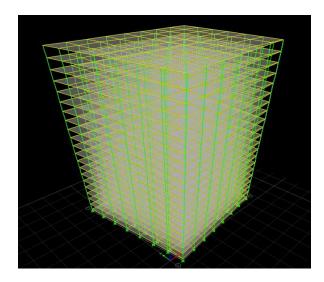

Figure 1.2-3D View of Tower

1.2 TIME PERIOD

IS-1893-2016 defines different Sa/g values for different values of approximate time period (T).

The natural time period (T) for building with non-structural walls made up of masonry can be calculated by the following formula.

$$T = 0.09 * \frac{h}{\sqrt{d}}$$

Base dimension \sqrt{d} in the direction along the considered direction on shaking (Global X and Global Y) vary with the change in orientation of the building.

Time Period	Tower 1	Tower 2
Global X	0.9107 sec	0.9076 sec
Global Y	0.9736 sec	0.9776 sec

1.3 DESIGN BASE SHEAR

The design base shear (V_B) of any building can be calculated by using the formula given in IS-1893-2016: $V_B = A_h * W$

Where A_h = Design horizontal seismic coefficient W = Seismic weight of the building

The Design horizontal seismic coefficient (A_h) is a function of peak ground acceleration (z), Importance Factor (I), Response Reduction Factor (R) and Design acceleration coefficient (S_a/g) for different types of soil normalized corresponding to 5 % damping.

$$Ah = \frac{2}{2} * \frac{1}{R} * \frac{3a}{g}$$

Sa/g values for medium soil according to IS-1893-2016,

 $\begin{cases} 2.5 \ for \ 0 < T < 0.55 \ sec \\ \frac{1.36}{T} \ for \ 0.55 \ < T < 4.0 \ sec \\ 0.34 \ for \ T > 4.0 \ sec \end{cases}$ $\frac{S_a}{g} =$

RESULT, ANALYSIS AND CONCLUSIONS

1) Approximate Time Period of Tower 1 and Tower 2 are different due to different base dimension in the direction of earthquake shaking.

For the Tower 1, base dimension along Global X is 40 m and 35 m in Global Y direction. For the Tower 2, base dimension along Global X is 40.3 m and 34.7 m in the Global Y direction. The Time period for Tower 1 in the Global X direction is 0.9107 seconds and in the Global Y direction is 0.9736

seconds. For the Tower 2, the Global X direction is 0.9076 seconds and in the Global Y direction is 0.9776 seconds.

2) Design Base Shear (V_B) is dependent on the S_a/g values. It is observed that the values of S_a/g are different for Tower 1 and Tower 2 in the Global X and Global Y directions.

Base Shear changes from 32026 KN in Tower 1 to 32144 KN in Tower 2 in the Global X direction. Also Base Shear changes from 29957 KN in Tower 1 to 29843 KN in Tower 2 in the Global Y direction.

3) It has been observed that Story Stiffness of Tower 2 is more than the Story Stiffness of Tower 1 as shown in Table 1.3 and 1.4. Story stiffness is calculated by the formula 12EI/h³ and moment of Inertia, I changes along its axis of consideration.

4) Impact of Orientation of building on Response Spectrum Analysis can be seen by Modal Direction Factors in Table 1.5 and 1.6. It is clear from Modal Direction Factors that the building behaves differently when it is rotated by 7° as in Tower 2, than its normal configuration as in Tower 1.

The first two modes are translational and third mode is rotational in nature. For the Tower 1, directional factors of the fundamental mode of oscillation are 0.128 in Global X and 0.798 in Global Y direction. However for the Tower 2, the directional factors of the fundamental mode of oscillation are 0.226 in Global X and 0.7 in Global Y direction.

5) Also from the Figure 1.5 and 1.6, it can be seen that the Time Period for the fundamental mode of oscillation changes for Tower 1 and Tower 2.

For the Tower 1, the Time Period for the fundamental mode of oscillation is 4.982 seconds whereas for the Tower 2, the Time Period for the fundamental mode of oscillation is 4.981 seconds.

6) Similarly variation is also observed in Modal Participating Mass Ratios as seen in the Table 1.7 and 1.8. In the fundamental mode of oscillation, participating mass ratio is 9.87% in Global X direction, whereas in Global Y direction the participating mass ratio is 61.38% in Tower 1.

For Tower 2, the modal participating mass ratio in Global X is achieved about 17.4% and 53.84% in Global Y direction.

7) Maximum Story Displacement is more in Tower 1 as compared to Tower 2 in the first mode of oscillation as shown in Table 1.9 and 1.10.

8) Column Design Forces are more in Tower 2 as compared to Tower 1 as shown in Table 1.11 and 1.12.
