Abstract - This paper, enlightens the effect of providing baffle walls in circular water tanks to suppress or minimize the effect of sloshing and hence studying the dynamic response of circular water tank for earthquake loading. As the water tanks are very important life line structures which needs to be survived after any type of disaster. To increase the performance of the circular water tanks, baffle walls can be effectively provided. In this work two types of baffle walls i.e. vertical and ring baffle wall is considered. The numerical study is done with the help of finite element model of tank-fluid system using ANSYS software. Also, Dynamic analysis is carried out for models with and without baffle wall and the results are plotted.

Key Words: Circular tank; Sloshing; Hydrodynamic; Baffle, CFD

1. INTRODUCTION

Sloshing is characterized by the oscillation of the unrestrained free surface of the liquid in a partially filled container due to external excitation. Slosh refers to the movement of one liquid inside another object under motion. The frequently causing main reasons of failure of water tanks are,

- 1) Sloshing effects of liquid and flexibility of container wall is not considered properly while evaluating the seismic forces on tanks.
- 2) It is documented that tanks are less ductile and contain low energy absorbing capacity as well as redundancy as compared to the conventional building system and other structures which is not considered properly.
- 3) Improper design and wrong selection of supporting system and under estimated or over estimated strength of the tank.

Baffles are commonly used as effective means of suppressing the magnitudes of fluid slosh, apart from enhancing the integrity of the tank structure.

Two types of baffles can therefore be distinguished:

- (i) Solid baffles, used as obstructions perpendicular to the flow to change the direction of the flow.
- (ii) Perforated baffles, used to break up the main jet into a more uniform current over a larger area

without the deliberate intention to change the direction.

2. OBJECTIVE AND FORMULATION

In this paper, effect of various types of baffle walls in circular water tank to suppress the sloshing is analysed. The methodology of this work is as under:

- Carrying over necessary literature survey.
- Water tank parameters such as geometry (circular), material of tank (Concrete / steel), type of tank (resting on ground) is selected.
- Based on expected capacity of tank, size of tank i.e. diameter and height of tank is to be selected.
- Type of baffle wall i.e. material, placement of baffle wall shall be selected.
- Compute natural frequency, time period and respective mode shapes of circular water tank with and without baffle wall.
- Modeling of circular tank with and without baffle wall and its analysis using ANSYS
- Comparing numerical analysis results of various types of baffle wall with tank without baffle wall. And comparing variation in total deformation, normal stress, shear stress and bending stress due to use of baffle wall
- Checking design parameters such as effect of opening, height of baffle wall.

3. CODAL PROVISIONS

IS 1893:2002-Part 2 is used for calculation of dynamic response of water tank. Along with hydrostatic forces, hydrodynamic forces exerted by liquid on tank wall, shall also be incorporated in the analysis for the water tanks. Spring-mass model is used to estimate this hydrodynamic force.

If a liquid tank vibrates along with liquid, the liquid exerts both impulsive as well as convective hydrodynamic pressures on tank wall and base of the tank, together with the hydrostatic pressure. To incorporate this effect of hydrodynamic pressure, in the analysis, tank is idealized by corresponding spring- mass model, which includes the effect of wall of tank and liquid interface. The various parameters of this model depends upon geometry and flexibility of the tank.

Fig-1 : Spring Mass Model for Circular Tank
(Ref: IS 1893 Part II)

For circular water tanks, parameters m_i , m_c , h_i , h_c etc can be obtained as per graphs given in IS -1893 Part II. As shown above, in spring mass model of tank for circular tanks, h_i is the height where resultant of impulsive hydrodynamic pressure on wall is situated from bottom of the tank wall. Whereas h_i^* is the height, at which point, the resultant impulsive pressure on wall and the base is positioned from the tank wall bottom. Consequently, if, base pressure effect is not considered, m_i , impulsive mass of liquid will act at a height of h_i from internal face of tank and if base pressure effect is considered, m_i^* will act at a height h_i^* from internal face of tank.

In the same way, h_c is the height, where, resultant convective pressure on wall is located from bottom of the tank wall, while, h_c^* is the height at which point, resultant of convective pressure on wall and base is located. Heights h_c , h_c^* are described in Figures. Hence, the value of h_i and h_c shall be used to calculate moment due to hydrodynamic pressure at the bottom of the tank wall.

4. PROBLEM STATEMENT

A circular reinforced concrete water tank without roof of capacity 3600m³ is resting on ground. Tank is situated above strata of soft soil in seismic zone IV. Analyze the tank for seismic loads. Various parameters considered for tank are as follows:

- **Properties of tank**

Inside Dia of Tank	14640mm
Height of tank	21920mm
Tank Wall Thickness	300mm
Base Slab Thickness	400mm
Grade of concrete	30
Volume of water	3600m ³
Mass of Water (M)	3600000Kg

For this Tank CFD analysis is carried out using ANSYS.16. Results are as follows

5. FEA MODEL ANSYS.16

Using FEA tool following models are analyzed

Model 1: Circular water tank without baffle wall

Model 2: Circular water tank with horizontal ring baffle wall

Model 3: Circular water tank with 1/3rd height vertical baffle wall

Model 4: Circular water tank with 1/2 height vertical baffle wall

Model 5: Circular water tank with 2/3rd height vertical baffle wall

Model 6: Circular water tank with 1/3rd height vertical baffle wall with single circular opening

Model 7: Circular water tank with 1/3rd height vertical baffle wall with multiple circular openings

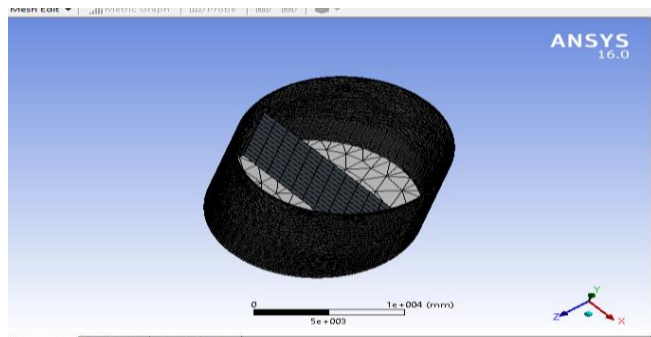

Fig-4: Finite element Mesh of vertical baffle wall

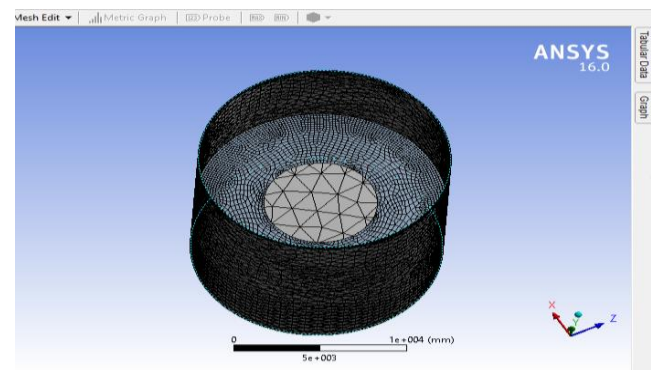

Fig-5: Finite element Mesh of ring baffle wall

5.1 Effect due to provision of Baffle wall

Table -1: Values of Total Deformation for CFD Analysis

Total Deformation			
	Tank without Baffle wall	Tank with ring Baffle wall	Tank with vertical Baffle wall
Top	0.52509	0.21356	0.14972
Middle	0.74914	0.18721	0.12751
Bottom	1.2271	0.034984	0.0070307

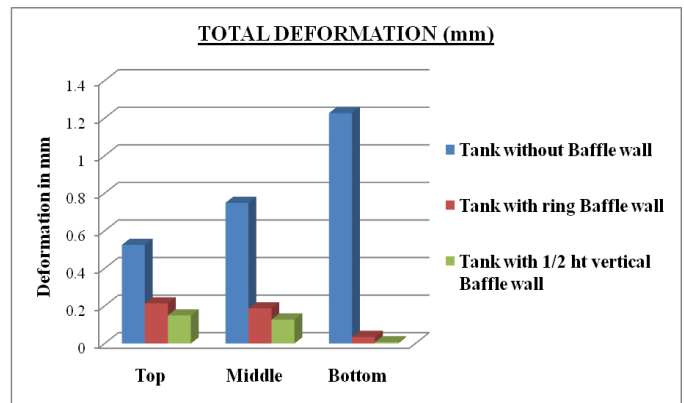

Chart-1: Graphical representation of Total deformation for CFD Analysis

Table- 2: Values of Normal stress for CFD Analysis

Middle	0.002589	0.0023979	0.0015305
Bottom	0.0368	0.001706	0.0012665

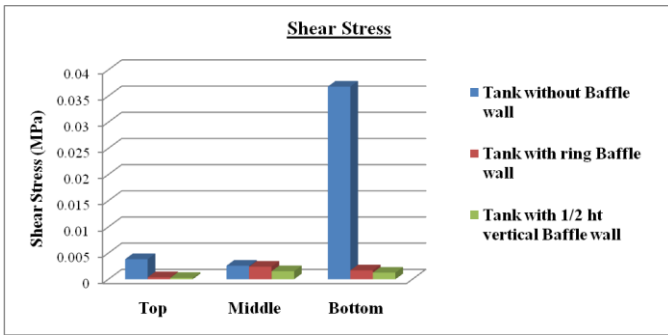

Chart-3: Graphical representation of Total deformation for CFD Analysis

Chart-5: Graphical representation of Normal stress for height variation

5.2 Effect of variation in height of baffle wall:

Further, to study the effect of height of baffle wall three models with different height of baffle wall are prepared and analyzed. The results are as shown below:

Table-4: Values of Total Deformation for CFD Analysis for height variation

Total deformation			
	Tank with 1/3 ht vertical Baffle wall	Tank with 1/2 ht vertical Baffle wall	Tank with 2/3 ht vertical Baffle wall
Top	0.17177	0.14972	0.17151
Middle	0.13927	0.12751	0.14328
Bottom	0.0104	0.0070307	0.05184

Table-6: Values of shear stress for CFD Analysis for height variation

Shear Stress			
	Tank with 1/3 ht vertical Baffle wall	Tank with 1/2 ht vertical Baffle wall	Tank with 2/3 ht vertical Baffle wall
Top	0.001003	0.0002601	0.0012197
Middle	0.0016503	0.0015305	0.0012177
Bottom	0.010016	0.0012665	0.0016261

Chart-4: Graphical representation of Total deformation for height variation

Table-5: Values of Normal stress for CFD Analysis for height variation

Normal Stress			
	Tank with 1/3 ht vertical Baffle wall	Tank with 1/2 ht vertical Baffle wall	Tank with 2/3 ht vertical Baffle wall
Top	0.0009532	0.0003913	0.0010595
Middle	0.00053362	0.00086345	0.0010516
Bottom	0.0013821	0.00025673	0.0022397

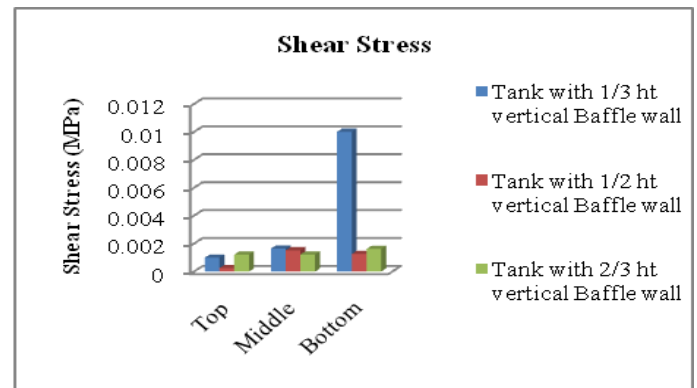

Chart-6: Graphical representation of Shear stress for height variation

From above three graphs, it can be seen that half height baffle wall tank has lesser values of deformation and stresses as compared to other three models.

5.2 Effect of opening in vertical baffle wall:

Afterwards, the effect of opening is analysed for models with centrally equally spaced 3m diameter single circular and multiple (03 Nos) circular openings at vertical baffle wall. The geometry of the water tank with single circular and multiple circular i.e. 03 Nos openings is as shown below:

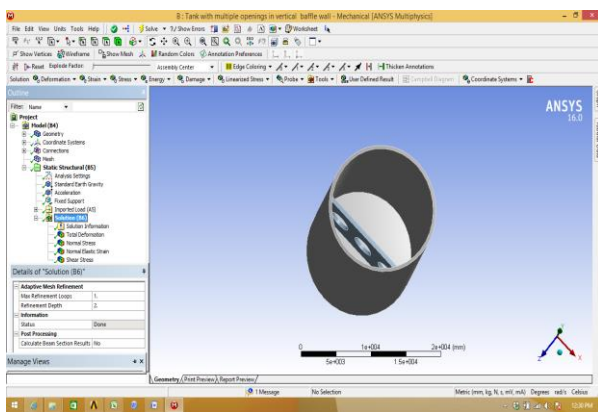

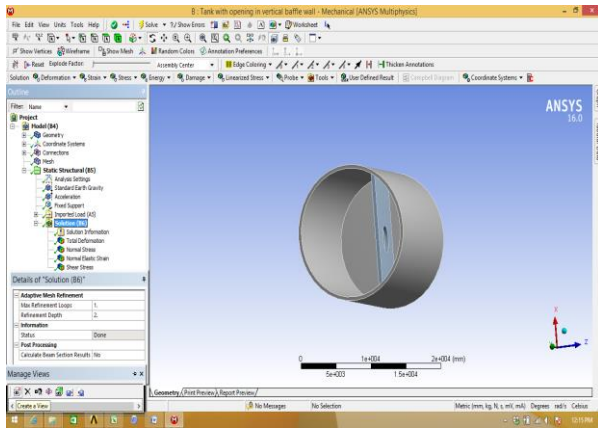

Fig-6: Geometry of baffle wall with openings for CFD Analysis

Table-7: Values of Total Deformation for CFD Analysis for effect of opening

Total deformation			
	Tank without opening in vertical Baffle wall	Tank with single opening in vertical Baffle wall	Tank with Multiple opening in vertical Baffle wall
Top	0.14972	0.17932	0.17662
Middle	0.12751	0.13175	0.13137
Bottom	0.0070307	0.02725	0.022559

Chart-7: Graphical representation of Total deformation for effect of opening

Table-8: Values of Normal stress for CFD Analysis for height variation

Normal Stress			
	Tank without opening in vertical Baffle wall	Tank with single opening in vertical Baffle wall	Tank with Multiple opening in vertical Baffle wall

Middle	0.00053362	0.0011314	0.001684
Bottom	0.0013821	0.0027791	0.0033944

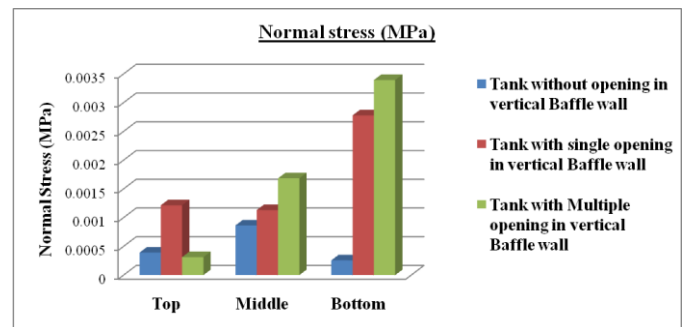

Chart-8: Graphical representation of Normal stress for effect of opening

Table-9: Values of Shear stress for CFD Analysis for effect of opening

Shear Stress			
	Tank without opening in vertical Baffle wall	Tank with single opening in vertical Baffle wall	Tank with Multiple opening in vertical Baffle wall
Top	0.001003	0.00011461	0.00018297
Middle	0.0016503	0.00033877	0.001353
Bottom	0.010016	0.00087828	0.013474

Chart-9: Graphical representation of Shear stress for effect of opening

6. CONCLUSIONS

Numerical study on circular water tank with and without baffle wall is carried out for hydrodynamic forces and past earthquake data. From all the above results and graphical representations, it can be seen that baffled tank increases the performance of circular water tank. From the trends of the numerical results of the present study, the following conclusions may be drawn:

- Total deformation of tank reduces in both vertical and ring baffled tanks than tank without baffle wall.
- Normal stress, shear stress and Equivalent stresses at various locations of tank are lesser in tank with baffle wall than tank without baffle wall by more than 60%.
- From comparison of height of baffle wall, it is concluded that one half height baffle wall has less deformation by about 32% and stresses are less by 60 to 80% than baffle wall of one third or two third height of tank.
- From comparison of effect of opening in baffle wall, it is concluded that provision of opening is not recommended as it results in swirl effect and increases stresses

ACKNOWLEDGEMENT

I express my sincere gratitude and respect to my project guide Prof. S L Bhilare and Prof. G. R. Patil, Professor of Structure (Civil) department, Rajarshi Shahu college of Engineering, Pune for their valuable suggestions, timely support and encouragement. I thank them for numerous useful suggestions apart from valuable guidance to me.

I would like to convey my sincere gratitude to my friends, colleagues and all the staff members of Structure (Civil) Department for their support and encouragement. The meaning of work is incomplete without paying regards to my respected parents and family whose blessings and continuous encouragement have shown me the path to achieve my goals.
