\*\*\*

**Abstract** - Concrete may be cast into bricks, blocks, and other relatively small building units, which are used in concrete construction. Concrete has a great variety of applications because it meets structural demands and lends itself to architectural treatment. The consumption of water is more for the concrete for its mixing and curing. Because of the scarcity of water now a days the alternate use of water for the concrete is made by considering two types of secondary treated water that is conventional and non-conventional treatment. Comparing the compressive strength of normal grade of concrete made by portable water with the secondary treated conventional and non-conventional type for different mix proportions of 0.35, 0.4 and 0.45 water cement ratios for 7, 14 and 28 days the optimum type of secondary treated water is used for the concrete for its mix and also for its curing.

**Key Words:** Concrete, Compressive Strength, Conventional water, Non-Conventionally treated water, Mix design, etc

## 1. INTRODUCTION

Concrete is the most commonly used building material. It has the advantage of being formed into any desired shape most conveniently. It is an artificial stone obtained by mixing aggregates, cement and water allowing these product to cure for hardening. The fine and coarse aggregates in a concrete mix are the inert, or inactive, ingredients. Cement and water are the active ingredients. Its essential ingredients are cement and water which react with each other chemically; to form another material having the useful strength. The strength of concrete depends upon the quality of its ingredients, their relative quantities and the manner in which they are mixed, compacted and cured. Concrete is the premier construction material across the world and the most widely used in all types of Civil Engineering works. Concrete, its total consumption is around twenty billions tones, which is equivalent to two tones for every living human being.

## 2. NEED AND OBJECTIVE OF THE STUDY

The first requirement for good concrete is to use a cement type suitable for the work at hand and have a satisfactory supply of sand, coarse aggregate, and water. Everything else being equal, the mix with the best graded, strongest, best

shaped, and cleanest aggregate makes the strongest and most durable concrete.

## 2.1 Need for the Study

The need of a sustainably developed and environmental friendly concrete is aggravated by population growth and scarcity of water. The world population doubled from 1959 to 1999, increasing from 3 billion to 6 billion. According to the US Census Bureau, the world population is projected to reach nine billion by 2043. Thus it is expected that water recycling and conservation as a necessity.

## 2.2 Objectives

- To investigate the impact of conventionally and non-conventionally treated waste water for mixing and curing of concrete cube.
- To compare the compressive strength of the casted cubes for tap water, conventionally and non-conventionally treated waste water.
- To replace the usage of fresh water by treated water in the concrete mix.
- To get comparative analysis of test results.

## 3. MATERIALS AND ITS PROPERTIES

i. Portland cement is the most common type of cement in general usage.

Normal consistency of cement = 31%

Fineness = (Mass of residue in gms/100) = 1.8%

Initial setting time of cement sample is found to be 45 min

Final setting time of cement sample is found to be 325 min

Specific gravity of cement = 3.24

ii. Coarse Aggregate

Specific Gravity of coarse aggregate is 2.63

Water Absorption = 0.67%

iii. Fine aggregate

Specific Gravity of coarse aggregate is 2.6

The fine aggregate confines to zone I

iv. Water

In this study both conventionally and non-conventionally treated waste water is used and its properties are given in the table.

**Table 3.1** Basic tests results on treated waste water

| Sl no | Parameters             | Tap Water    | NC treated waste water | Tolerable Limits |
|-------|------------------------|--------------|------------------------|------------------|
| 01    | pH                     | 8.1          | 7.25                   | 6.8              |
| 02    | Alkalinity             | 545mg/l t    | 210 mg/lt              | 250 mg/lt        |
| 03    | Acidity                | 28mg/lt      | 10 mg/lt               | 50 mg/lt         |
| 04    | Total Hardness         | 600mg/l t    | 330 mg/lt              | -----            |
| 05    | Total Suspended Solids | 300mg/l t    | 5 mg/lt                | 2000mg/lt        |
| 06    | BOD                    | 59mg/lt      | 7 mg/lt                | -----            |
| 07    | COD                    | -----        | 26 mg/lt               | -----            |
| 08    | DO                     | 15.82mg /lt  | 5.8 mg/lt              | -----            |

**4. BRIEF DESCRIPTIONS OF THE PLANTS INCLUDED IN THE SCOPE OF WORK:**

i. Conventional type

The V-Valley sewage treatment plant has been constructed to treat sewage generated in the western part of the city. Capacity of the treatment plant is 180MLD. This treatment plant is situated near Nayandahalli Bangalore-Mysore road. The treatment process involved in this plant is “Conventional two stage trickling filter process”.

ii. Non Conventional type

The 75 MLD secondary sewage treatment plant was constructed to treat the wastewater. The plant is designed to treat the sewage of the above said qualities for the flow/capacities as mentioned below are expected up to the year 2011. The plant bagged the “ICI-(KBC)-Birla Plus Endowment Award” for outstanding concrete structure of Karnataka for the year 2004.

**Table 4.1** Characteristics of waste water in treatment plant (conventional type)

| PARAMETERS                   | INFLOW (mg/l) | OUTFLOW (mg/l) |
|------------------------------|---------------|----------------|
| Total Suspended Solids (TSS) | 615           | <5             |
| BOD                          | 412           | <5             |
| COD                          | 820           | <20            |
| DO                           | Nil           | 4              |
| pH (unit less)               | 6.9           | 7 to 8         |

**Table 4.2** Characteristics of waste water in treatment plant (non conventional type)

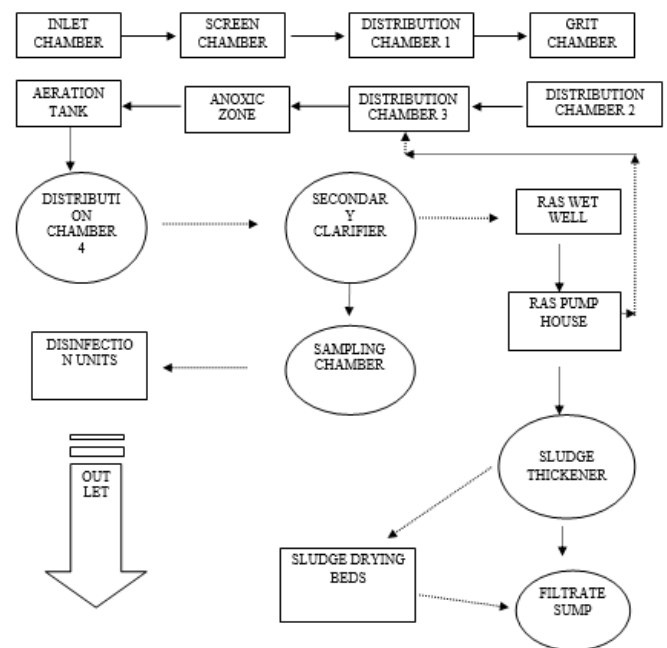

| PARAMETERS                      | INFLOW (mg/l) | OUTFLOW (mg/l) |
|---------------------------------|---------------|----------------|
| Total Solids                    | 1050          | 520            |
| Total Suspended Solids (TSS)    | 230           | 7              |
| BOD                             | 350           | 7.25           |
| COD                             | 608           | 42             |
| Chlorides (as Cl)               | 137           | 128            |
| Sulphates (as SO <sub>4</sub> ) | 42            | 16             |
| pH (unit less)                  | 7.18          | 7.40           |

- Sludge pumping

Secondary Treatment Units:

- Secondary bio-filters
- Secondary clarifiers
- Sludge digesters
- Sludge pumping
- Sludge drying bed

**5.2 Non-Conventionally treated water process**

**Fig 5.1** Flow chart showing Operational Units at Mailasandra 75 MLD STP

**5. CONVENTIONALLY AND NON-CONVENTIONALLY TREATED WATER PROCESS**

The major aim of waste water treatment is to remove as much of the suspended solids as possible before the remaining water, called effluents is discharged back to the environment. As solid materials decays, it uses up oxygen which is needed by the plants and animals leaving in the water. Primary treatment removes above 60% of suspended solids from waste water. This treatment also involves aerating the waste water, to put oxygen back in. Secondary treatment removes more than 90% of suspended solids.

**5.1 Conventionally treated water process**

Pre Treatment Units:

- Screening
- Gritting
- Primary clarifiers
- Primary bio-filters
- Recirculation pump house

**6. MIX DESIGN**

Mix design is carried out as per IS: 10262-2009 for M20 concrete by varying water cement ratio (0.4&0.45). The process of selecting suitable ingredients of concrete and determining their relative amounts with the objective of producing a concrete of the required, strength, durability, and workability as economically as possible, is termed the concrete mix design.

**Design stipulations for proportioning**

- Grade designation : M20
- Type of cement : OPC 53 grade conforming to IS 8112
- Maximum nominal size of aggregates 20 mm
- Minimum cement content : 300 kg/m<sup>3</sup>
- Maximum water cement ratio : 0.5
- Workability : (25-50)mm (slump)

- Exposure condition : Moderate
- Degree of supervision : Good
- Type of aggregate : Crushed angular aggregate
- Maximum cement content : 450 kg/m<sup>3</sup>

**Table 6.1** Mix proportions of different w/c

|                                       |                 |                 |                |
|---------------------------------------|-----------------|-----------------|----------------|
| WATER CEMENT RATIO                    | 0.35            | 0.4             | 0.45           |
| CEMENT (kg/m <sup>3</sup> )           | 450             | 450             | 413.33         |

### 7. MIXING, CASTING AND CURING

All the ingredients required for the preparation of concrete were effectively mixed manually (hand mixing) on a large steel tray. First, all the dry ingredients such as cement, fine aggregates, coarse aggregates and polyester fibers and steel fibers were mixed for 3 minutes, after which water was added based on the quantity determined from the mix design and then all the ingredients were mixed thoroughly for about 4 minutes.

15 concrete cubes will be casted according to the mix proportions and by varying water cement ratio (0.35,0.4&0.45). For M20 concrete different combination of concrete mixing will be carried out as given below  
 5 Specimens are casted using 100% tap water.  
 5 Specimens are casted using 100% conventionally treated waste water.  
 5 Specimens are casted using 100% non-conventionally treated waste water.

Curing will be done by immersing the specimens in curing ponds of tap water and treated water separately. Three curing ages are selected i.e 7,14,28 days. Three concrete blocks are tested for compressive strength at single ag

### 8. TEST RESULTS

**Table 8.1** Average Compressive strength of concrete (Tap water as mixing and curing water)

| Water cement ratio | Curing age (days) | Sl no | Weight of cube (kg) | fck (N/mm <sup>2</sup> ) | Avg comp strength (N/mm <sup>2</sup> ) |
|--------------------|-------------------|-------|---------------------|--------------------------|--|
| 0.35               | 7                 | 1     | 8.18                | 18.44                    | 18.538                                 |

## 9. CONCLUSIONS

- The normal consistency, initial and final setting time of cement paste by mixing Secondary treated waste water Within the IS limit.
- The compressive strength of portable treated water and secondary treated water is compared in all the water cement ratios.

- Tests performed in this study suggest that Non conventionally treated waste water is an interesting candidate for using concrete for applications in the mixture and curing.
- The compressive strength of non conventionally treated water concrete of 0.35,0.40 and 0.45 water cement ratio is more compared to the conventionally treated water in all the ratios.
- For 0.45 water cement ratio the compressive strength of non conventionally treated waste water is almost same as the portable treated water for 14 and 28 days.
- When compared to three water cement ratios (0.35,0.4 and 0.45) 0.45 water cement ratio is found to be efficient in using it in concrete mix and curing for treated water.
