

Design and Fabrication of a Self Balancing Mono Wheel Vehicle

Abhishek kaushal

B.E Student, Department of Mechanical Engineering, RGTU University, Bhopal, Madhya Pradesh, India

ABSTRACT: The 'Single Wheel Hover-board' is a personal electric vehicle running on a single wheel. The vehicle is powered by a battery source. The motor (DC 24V, 250W, High Torque) is in skew with the shaft of the wheel with the help of a chain drive, whose speed will be controlled by a custom designed 'Speed control' circuit, capable for currents about 50A. The control of the motor direction is the posture of the persons driving it. Intelligent sensors like IMU, which houses accelerometer and gyroscope is used to monitor the posture of the person and accordingly the processor signals the speed controller circuit. Additional features for the Hover-board includes the regenerative braking, inbuilt battery charging capability, battery level indicator.

KEYWORD: Hoverboard, Chopper drive, Electric Vehicle, PID controller

I. INTRODUCTION

With the alarming rate of depreciation of fossil fuel level and the increasing carbon footprint per person, the advent to more sustainable means of transportation is crucial for the longevity of the present resources. The world has two important reasons to switch our transportation options for the sake of longevity of the world we know.

The first reason has apparently surfaced up recently after a long time. According to a Morgan Stanley report, the efficiency of a General Electric gas turbine at a thermal electric power plant achieves ~66% efficiency. On the other hand, Internal Combustion engine on an average (2 stroke and 4 stroke) scores about 27% efficiency [10]. With same source fuel, the data collected from them is a stark contrast. The reason is Combustion engine operates in fixed constraint boundary, ranging from weight, cylinder arrangement etc. Whereas, a power plant can be afforded to have additional components, like secondary generator that makes use of the flue steam, and thus adds up to the efficiency.

The "Single Wheel Hover-board" is a personal electric vehicle, suited for casual and short commutation. It's a vehicle that balances on a single wheel, and operates according to the direction of inclination of the driver (forward and backward).

II. LITERATURE SURVEY

The project required survey and learning exposure to some related projects. The following projects were referred.

A. Two-Wheeled Balancing Robot Controller Designed Using PID [2]

In this paper, the use of PID Controller with IMU Sensor for an elevated wheeled-platform was justified. The paper deals with counteracting with effect of gravity on the platform. The PID Controller was deployed to sense the inclination of the platform against the ground level, and compute control variables for counteract the fall with providing sufficient counter-torque, so that the platform stays parallel with respect to ground.

B. Speed Control Of D.C. Motor Using Chopper [11]

The use of chopper drive was observed in the paper. The performance of the four-quadrant chopper drive is observed, which concludes the effectiveness of the driver for closed loop operation.

C. DESIGN AND DEVELOPMENT OF A PROTOTYPE SUPER-CAPACITOR POWERED ELECTRIC BICYCLE [8]

The use of PMDC motor for traction purpose, instead of the traditional BLDC motor is justified in this paper. The paper deals of equipping a bicycle with a PMDC Motor and Super-Capacitors for long-distance commute. The motor driver exhibits regenerative braking, which is a significant feature of our project.

D. SELF BALANCING SCOOTER ^[9]

This final year project is important from the standpoint of our project. The project gives a clear picture of the physics, coding and electronics required to make a self-balancing Macro-entity. The project deals with the use of higher traction DC motors, critical operation of the motor driver and its safety, and complexity of the coding to implement self-balancing operation.

III. PROPOSED DESIGN

The block diagram below represents the components and function flow between each of them.

Fig.1. Functional Block Diagram

The description of the components is as follows:-

A. Motor

The motor used is a PMDC motor, which offers a good speed-torque characteristics and costing low. ^[1] The specifications of the motor are as follows :-

Rated Power	250W
Rated Voltage	24V DC
Rated Speed	2650 RPM
No Load Speed	3000 RPM
Full Load Current	≤13.7A
Rated Torque	0.80 N.m (80 Kg.cm)
Stall Torque	0.50 N.m (50 Kg.cm)
No load current	≤2.2A
Efficiency	≥78%

Table 1. Motor Specifications

Fig 2. 250W DC Motor

B. Motor Driver

The motor driver is a four-quadrant chopper. This enables the board to perform forward motoring and regenerative modes, and reverse motoring and regenerative modes. ^{[5] [6] [11]}

Features :-

- ☑ Bi-directional control for 1 brushed DC motor.
- ☑ Motor Voltage: 5V - 30V.
- ☑ Maximum Current: 80A peak (1 second), 30A continuously.
- ☑ Reverse polarity protection.
- ☑ 3.3V and 5V logic level input.
- ☑ Fully NMOS H-Bridge for better efficiency and no heat sink is required.

C. IMU Sensor

The inclination of the driver is sensed by a component called Inertial Measurement Unit (IMU) MPU6050. It houses 3-DOF Accelerometer and 3-DOF Gyroscope.

The MPU 6050 is a 6 DOF which means that it gives six values as output. This chip uses I2C (Inter Integrated Circuit) protocol for communication. The module has on board Digital Motion Processor (DMP) capable of processing complex 9-axis Motion-Fusion algorithms.

Fig.3. IMU Connection to Arduino

1. Inverted Pendulum Test Case

The computation of control variables is sampled by a mathematical model of a classical physics test-case called "Inverted Pendulum". ^[7]

Fig.4. Inverted Pendulum diagram

$$\alpha = \frac{a \cos \theta + g \sin \theta}{l}$$

Those accelerations are integrated to compute the linear velocities, and angular velocities, which are then integrated to compute the linear position and angle of the balance bot.

2. Smoothing of IMU outputs

The telemetry of the IMU sensor was disturbed by the mechanical vibrations, which led the IMU to produce noisier responses to the microcontroller. The IMU was padded with absorptive materials, like sponge and rubber pads. These IMU was fixed onto the sponge padding and fixed on the frame to absorb vibrations. The response of the IMU improved.

Fig 5.Sponge padding of IMU

D. PID Controller

The control algorithm that is used to maintain its balance position on the self-balancing two wheel robot was the PID controller. The proportional, integral and derivative (PID) controller is well known as a three term controller. The Proportional Integral Derivative (PID) controller is a control loop feedback mechanism that is widely used in the industry. The controller attempts to adjust and correct the error between the measured process and the desired process and output corrective measures to adjust the process accordingly. [2]

Response	Rise Time	Overshoot	Settling Time	Steady State Error
Kp	Decrease	Increase	Small Variation	Decrease
Ki	Decrease	Increase	Increase	Eliminated
Kd	Small Change	Decrease	Decrease	No change

Table 4.1:- Effect of PID Constants

1. PID Algorithm

The PID algorithm accepts the real time values from the IMU sensor, namely the acceleration and gyro-rates, and computes the steady state error with reference to a set point, in our case 180°. The PID controller then applies its control on the PWM values to the motor in order to correct the error and hence balance the platform.

Fig 7. Balance Algorithm

The response of the PID controller is all dependent on the weightage we assert on certain computing variables. The weightages are called as PID constants, namely Kp, Kd and Ki. The Fig 8 shows a simple representation of the concept of self-balance.

Fig 8. Pictorial representation of Balancing platform

The basic algorithm of PID controller is as follows:-

$$\text{Error} = \text{Current Reading} - \text{Setpoint}$$

$$\text{Error} = \text{Setpoint} - \text{Current Reading}$$

Below are the equations involved in calculating the output PID:

$$\text{Output Proportional Term} = K_p * \text{Error}$$

$$\text{Output Integral Term} = K_p K_i * \text{Summation of Error} * T = K_p K_i T * (\text{Summation of Error})$$

Output Differential Term = $K_p * K_d * (\text{Error} - \text{Previous Error}) / T = (K_p * K_d / T) * (\text{Error} - \text{Previous Error})$ The simplification of the formula is as below.

$$\text{Output Proportional Term} = K_p * \text{Error}$$

$$\text{Output Integral Term} = K_i * (\text{Summation of Error})$$

$$\text{Output Differential Term} = K_d * (\text{Error} - \text{Previous Error})$$

Overall, the output PID controller for balancing control system will be:

$$\text{Output PID controller} = \text{Output Proportional Term} + \text{Output Integral Term} + \text{Output Differential Term} \quad [9]$$

2. PD Tuning

The tuning of the PID controller is required to optimize the balance algorithm. The initial PID constants of the algorithm were fixed at lowly values. In-order to change the values of the constants K_p and K_d on the go, we devised a circuit which consists of two potentiometers, each meant for the two constants. [2]

Fig 9.Circuit to manipulate PD constants

The potentiometers, as in Fig 9, were turned on the go by observing the behavior of the board. The microcontroller read the analog values from the potentiometers, and accordingly updated the values of the PD constants. Each constant affects the system in different ways:-

- ☐ Increasing K_p improves rise time, while worsening settling time.
- ☐ Increasing K_d improves rise time, overshoot, and settling time (to a point).
- ☐ Increasing K_i improves steady-state error, but can have undesirable effects on the controller.

The Integral constant was decided to kept constant. While it improves the steady state error, slight mismatch leads to its dominance over other constants, which makes the system to react rather erratically to input values. The following steps were taken to tweak the PD constants:-

- ☐ Set $K_p = K_d = 0$.
- ☐ Adjust K_p until the system remains in balance, but rapidly oscillates around equilibrium.

IV. OBSERVATIONS

The Single wheel hoverboard responds well to the user inclination. The Fig 13 shows the fully assembled vehicle. The response of the PID algorithm requires little more tuning driving at high speeds. At low speeds, the hoverboard gives sufficient inclinatory response, which suffices the user into an aerodynamic posture.

Fig 13.Lateral View of the Hoverboard

V. CONCLUSION AND FUTURE WORK

The hardware is performing the balancing function in a hassle free manner with the user standing on it. The PID algorithm's response is just perfect and is intuitive enough for any new user to perceive the how-to for this hardware. The skateboard posture provides more aerodynamic and grip advantage over the current two-wheel-hoverboards available in the market. The inbuilt battery level indicator displays accurate readings of the charge remaining in the battery.
